Abstract

**Background and objectives:** The chemical composition of *Melanthera scandens* (MS) methanol (MeOH) extract is yet to be fully comprehended. Chemical composition of a plant extract is closely related to the biological activity of the plant material, in phytomedicine. In this study, chemical analyses of MS extracts were carried out with the aim of identifying the organic chemical constituents.

**Methods:** Powdered MS leaf was soxhlet extracted with dichloromethane and MeOH. The solvent extracts were analyzed using electrospray ionization-mass spectrometer and GC-MS (fatty acid methyl ester and trimethylsilyl derivatives). Fresh MS leaves were cold extracted with MeOH for biological studies and isolation of compounds. The MeOH extract was screened for phytochemical constituents and partitioned with *n*-hexane, ethyl acetate (EtOAc) and *n*-butanol to give the respective fractions. The *n*-hexane fraction was examined for volatile constituents using gas chromatography-mass spectrometry. Antibacterial study of *n*-hexane, EtOAc, butanol fractions and crude MeOH extract was undertaken; extract and fractions were screened against *E. coli*, *P. aeruginosa*, *B. subtilis*, *B. cereus* and *S. aureus*. The minimum inhibitory concentration and minimum bactericidal concentration of the EtOAc fraction (the most active) were determined using the macrobroth dilution method, and the fraction was subjected to column fractionation. Eluents were monitored by thin-layer chromatography. The combined fractions that exhibited antibacterial activity were further purified to obtain isolates which were characterized by spectroscopic techniques — nuclear magnetic resonance, Fourier transform infrared, gas chromatography-mass spectrometry (fatty acid methyl ester and trimethylsilyl) and electrospray ionization-mass spectrometer.

**Results:** Phytochemical screening of MS extracts showed the presence of alkaloids, tannins, cardiac glycoside, saponins and steroid, while flavonoid was not detected. The *n*-hexane fraction, EtOAc fraction, and crude MeOH extract inhibited the growth of *S. aureus*. The minimum inhibitory concentration and minimum bactericidal concentration of the EtOAc fraction identified 14 compounds, among which phytol acetate and trimethylsilyl) and electrospray ionization-mass spectrometer.

Keywords: *Melanthera scandens*; Antibacterial study; Asteraceae; Isolation.

eter analysis tentatively identified 5 triterpenoid glycosides.

**Conclusions:** The MEOH extract and its fractions, except the n-butanol fraction, inhibited the activity of *Bacillus* species considerably, from among the tested microbes, to varying degrees. A total of 54 different bioactive chemical compounds were identified in the leaf extract of MS. These compounds contribute to its biological activities, including antibacterial, thereby justifying its use in ethno-medicine to manage diseases caused by pathogenic microorganisms.

---

**Introduction**

*Melanthera scandens* (MS) belongs to the plant family Asteraceae and is found mostly in tropical regions, including Nigeria, Mexico, Central America, South America, and Sub-Saharan Africa. The common names are Aboyunrinnyun (Yoruba) and vine (English).

MS is a scrambling or scandent herb of waste thickets, cultivation edges and forest margins, commonly dispersed in the forested areas of the region. The plant is often confused with *Aspilia africana* and has almost the same uses. Herbalists use the juice of the leaves to stop dysentery. It is also used for the treatment of skin infections, gastroenteritis, and stomach ache, and as a diuretic and treatment for hypertensive activities. It is used against piles, diarrhea and hemorrhoids. Infusion or decoction of the leaves is used as an emetic, and cough and febrile headache medicine. In Côte d’Ivoire, the leaves are used as a purgative and an antidote against poisoning. In Nigeria, pulped, decoc ted or macerated leaves are used as hemostatic preparations, applied to cuts and wounds to promote healing and curb inflammation. Finally, the aerial part of MS is used as feed stock for rabbits.

Compounds in MS that have been previously reported include oleanolic acid (OA), 3-O-[β-D-glucuronopyranosyl-oleanolic acid (GrOA), 3-O-[β-D-xylpyranosyl(1→4)]β-D-glucuronopyranosyl]-oleanolic acid (XGrOA), 3-O-[(β-D-glucopyranosyl (1→2)] [β-D-xylpyranosyl(1→4)]β-D-glucuronopyranosyl]-oleanolic acid (GXGrOA), 3-O-[β-D-glucuronopyranosyl-28-O-β-D-glucopyranosyl-oleanolate (GrGOa), 3-O-[(β-D-glucopyranosyl (1→2)] [β-D-xylpyranosyl(1→4)]β-D-glucuronopyranosyl]-28-O-β-D-glucopyranosyl-oleanolate (GXGrGOa) and 3-O-[β-D-xylpyranosyl(1→4)]β-D-glucuronopyranosyl]-28-O-β-D-glucopyranosteryl-oleanolate (XGrGOa).

The current study aimed to investigate the organic chemical constituents of MS and bioactive fractionation of MS extract in order to identify phytochemicals responsible for activity.

**Materials and methods**

**Plant materials**

The leaves of MS were collected from Ogo-Oluwa farm, Ido-Ijesa, Osun State, Nigeria. The plant was identified and authenticated (voucher specimen number: FPI/2084) by Mr. I. J. Ogunlowo, Pharmacy Herbarium, Ile-Ife, Nigeria.

**Preparation of the extracts**

**Extraction for chemical analysis**

The MS leaves were dried at 60 °C for 48 h and milled to 1 mm particle size. Moisture content was determined in duplicate before extraction. The plant material was soxhlet extracted, first with dichloromethane (DCM) (150 mL) for 24 h and then with methanol (MeOH) (150 mL) for 48 h. The extracts were concentrated to dryness using a rotary evaporator. Extractives yields were 2.71% for DCM and 4.48% for MeOH.

Large-scale extraction for biological assay and compound isolation

The MS leaves were air dried and ground into fine powder. The powdered MS leaf (2.5 kg) was extracted (3 times) by steeping in MeOH (10 L) for 24 h and then filtered. The extract was concentrated to dryness to afford 150 g (6% yield) of crude extract. The crude MeOH extract (100 g) was dissolved in water (500 mL), partitioned sequentially with n-hexane (3 × 200 mL), ethyl acetate (EtOAc) (3 × 200 mL) and n-butanol (3 × 200 mL) using a separating funnel to give the respective solvent fractions.

**Phytochemical screening of the MS MeOH extract**

Qualitative phytochemical screening was carried out by standard procedure, based on earlier reports and described below.

**Test for flavonoids**

The MS MeOH extract (0.05 g) was dissolved in water (5.0 mL) and filtered. To the filtrate (1.0 mL), a few drops of ethanolic KOH solution were added. The resulting solution was examined for formation of suspension, cloudiness or precipitation characteristic of flavonoids.

**Test for tannins**

The MS MeOH extract (0.05 g) was dissolved in water (20 mL) and filtered. A few drops (2–3) of 0.1% ferric chloride in glacial acetic acid solution were added to the filtrate. The mixture was examined for the formation of brownish green or blue-back precipitate characteristic of tannins.

**Test for alkaloids**

The MS MeOH extract (0.05 g) was dissolved in water (20 mL) and then filtered. A few drops (2–3) of 10% (v/v) HCl added, boiled, and filtered. To each filtrate, separately, 1.0 mL of Mayer’s reagent, Wagner’s reagent, and Dragendorff reagent were added. The formation of a cream precipitate (with Mayer’s reagent), an orange precipitate (with Dragendorff’s reagent), or a reddish brown precipitate (with Wagner’s reagent) was regarded as indicating positivity for the pres-
Acetic anhydride (2 mL) and H\textsubscript{2}SO\textsubscript{4} (2 mL) were added to the Test for steroids before and after warming indicated the presence of saponin. The MeOH extract (50 mg) in a tube was suspended in water (2.0 mL) and shaken vigorously. The tube was then warmed to 70 °C and shaken vigorously again. The appearance and persistence of frothing before and after warming indicated the presence of saponin.

**Test for saponins (frothing test)**

The MeOH extract (50 mg) in a tube was suspended in water (2.0 mL) and shaken vigorously. The tube was then warmed to 70 °C and shaken vigorously again. If frothing is observed, it indicates the presence of saponins.

**Test for cardiac glycosides**

The MeOH extract (0.5 g) was dissolved in chloroform (2 mL) and filtered into a test tube. Concentrated sulfuric acid was carefully added to form a lower layer. A reddish brown to deep viscous brown indicated the presence of steroidal glycosides.

**Antimicrobial study**

Organisms

*Bacillus subtilis* (National Collection of Type Culture (NCTC) 8236), *Bacillus cereus* (NCTC), *Staphylococcus aureus* (NCTC 6571), *Pseudomonas aeruginosa* (American Type Culture Collection (ATCC) 10145) and *Escherichia coli* (ATCC 25922) were used in this study.

Testing of extract and partitioned fractions for antibacterial activity

The extract and partitioned fractions (40 mg/mL) were subjected to antibacterial tests (in triplicate) against five bacterial strains [(a) Gram positive (+ve): *B. subtilis*, *B. cereus*, and *S. aureus*; and (b) Gram negative (-ve): *P. aeruginosa* and *E. coli*) to access the broad spectrum activity of the extract. The cup-plate agar diffusion method was adopted to assess antibacterial activity of the prepared extract and partitioned fractions. Bacterial suspension (0.6 mL) containing approximately 10\(^5\) cfu/mL was thoroughly mixed with sterile nutrient agar (60 mL). The inoculated nutrient agar (20 mL) was distributed into sterile Petri dishes and bacterial inoculum broth (0.5 mL) was added to the respective Petri dishes. The contents of the Petri dishes were mixed thoroughly by rotary motion. The medium containing inoculum was allowed to solidify at room temperature.

After solidification of the medium, four wells of approximately 8 mm diameter (at equal distance) were cut with a sterile metallic borer. Uniform volumes of different concentrations of test solution and standard solution were added to the wells in the Petri dish and labeled. The solutions were allowed to diffuse by leaving plates undisturbed for 1 h at room temperature. The second plate containing dimethyl sulfoxide was used as a negative control. The Petri dishes were incubated at 37 ± 1 °C for 24 h and the zones of inhibition were recorded (in mm) for each of the extract and fractions.

**Determination of minimal inhibitory concentration (MIC)**

MIC was determined using the macrobroth dilution method in test tubes. Double-strength Mueller Hinton Broth (1 mL) was first dispensed into the tube, then 1 mL of sample solution (40 mg/mL) was added. Serial dilutions were made to obtain a final concentration of 0.025 mg/mL. A no-extract control sample served as the negative control, while another tube with ciprofloxacin (2 mg/mL) served as the positive control (being a broad spectrum antibiotic). The bacterial suspension (5 µL, ~10\(^5\) cfu/mL) was then added to each test tube. Another set of tubes containing broth was not inoculated and served as the noninoculated control. The experiment was carried out in duplicate and the tubes were incubated at 37 °C for 24 h. After the incubation period, samples from the tubes were subcultured on a dried duplicate Mueller Hinton Agar plate, applied using a sterile loop, before adding a drop of tetrazolium salt to each tube and inspecting for color change that indicates the presence of viable cells in the tubes. The minimum concentration inhibiting the growth of a test organism was recorded as the MIC of the test sample against the organism.

**Column chromatography**

A slurry of silica gel in n-hexane, free of air bubbles, was poured into a clean glass column (4 cm id × 55 cm) containing some n-hexane. The crude MeOH extract (10 g) was pre-adsorbed on silica gel (30 g) and effectively transferred into the prepared column. The column was initially eluted with 100% n-hexane (3 × 100 mL) and the eluent was collected in 20 mL portions. Gradient elution was carried out by increasing the amount of EtOAc from 0.5% to 100% and DCM/MeOH mixtures of increasing polarity. Elution was monitored using thin-layer chromatography (TLC) analysis. The TLC plates were observed by fluorescence under UV-light, followed by staining with iodine vapor. Fractions with identical TLC patterns were combined, and 18 combined fractions were obtained.

**Antibacterial screening of the combined fractions**

The combined silica gel column fractions were screened for antibacterial activity; the results are presented in Supplementary Table S1. All the 18 combined fractions were tested against *Bacillus* species (since *Bacillus* species were found to be responsive to the extract). Eleven combined fractions displayed remarkable activity.

**Further purification of combined fractions B, D, G, I and K**

Only five of the eleven bioactive combined fractions were available in appreciable quantity for further purification. Fraction B (0.41 g) was further fractionated by column chromatography (silica gel, mesh size 60–120). The column was eluted with solvent mixtures.
of n-hexane/EtOAc. Tubes 16–25 were combined on the basis of TLC pattern; a whitish solid precipitated, which on filtration was labeled B1/IIL (0.20 g). Fraction B1 was analyzed by electrospray ionization-mass spectrometry (ESI-MS), gas chromatography-mass spectrometry (GC-MS of the fatty acid methyl ester (FAME) and trimethylsilyl (TMS) derivatives), infrared spectroscopy and nuclear magnetic resonance (NMR). Combined fractions D, G, I and K were treated similarly and analyzed. From fraction D test tubes 15–22, a solid labeled D1/IEL (0.03 g) was obtained. Fraction G yielded two solids: test tubes 7–18, solid G1/IIL (0.01 g); and test tubes 25–34, solid G2/IML (0.08 g). Fraction I test tubes 18–25, contained solid I/IPL (0.08 g). Fraction K afforded two solids: test tubes 14–21, solid K1/IAL (0.02 g); and test tubes 28–35, solid K2/IIL (0.02 g).

**NMR spectroscopic analysis**

$^1$H-NMR spectroscopic data was recorded on a 300 MHz Agilent Technologies NMR Machine and 126 MHz for $^{13}$C-NMR. Chemical shifts of signals were reported in parts per million (ppm).

**GC analysis**

Gas chromatogram was recorded on Agilent Technologies 7890A and 5975C Mass Spectrometer using a HP 5 MS column (30 m $\times$ 0.32 mm $\Phi$, 25 μm). The analysis was carried out with temperature profile of 40 °C (1 min) to 320 °C (10 min) at 5 °C/min.

**ESI-MS experiment**

The samples (about 1.0 mg each of DCM and CH$_3$OH extracts and isolates in duplicates) were added to CH$_3$OH (1 mL) and acetic acid (10 μL). The mixture underwent sonication, to ensure total dissolution. Electrospray mass spectrometric analyses were performed on a Hewlett-Packard 5989A equipped with an electro-spray interface 59987A. Nitrogen was used as the nebulizing gas, at a pressure of 50 psi and a temperature of 300 °C. The samples were analyzed by direct infusion (10 μL/min) in scan mode.

**GC-MS analysis of extracts and isolates as TMS derivatives**

Extracts and isolates (1.0 mg, in duplicate) were weighed and added to GC vials, to which DCM (1 mL) containing antrancene as an internal standard (IS) (50 μg/mL) was added. The samples were silylated with addition of N,O-bis(trimethylsilyl)-trifluoroacetamide (BSTFA) containing 1% trimethylchlorosilane (TMCS) (50 μL) and pyridine (50 μL) and heated for 30 min at 70 °C or longer, until the solution became clear. The prepared TMS derivatives were analyzed by GC–MS EI (FOCUS-ISQ; Thermo Scientific, Waltham, MA, USA) using the following parameters: temperature profile: 40 °C (1 min) ramped to 305 °C (10 min) at 5 °C/min; GC capillary column (RTx-5 MS, 30 $\times$ 0.25 mm $\Phi$, Restek). The eluted compounds were identified by spectral matching with the 2008 National Institute of Standard and Technology (NIST) spectral library and known standards.

**GC-MS analysis of FAME derivatives**

Extracts and isolates (2.0 mg, in duplicate) were weighed and added to 5 mL vials, to which FAME reagent (2 mL; prepared by adding a solution of 1-naphthaleneacetic acid (100 μg/mL) in DCM (50 mL) to a mixture (50 mL) of MeOH/H$_2$SO$_4$ (1.7:0.3:2.0 v/v/v)) was added to each vial and heated for 90 min at 90 °C. 1-Naphthaleneacetic acid was the IS. The mixture was allowed to cool, after which water (1 mL) was added, and the sample was shaken vigorously and centrifuged. The CHCl$_3$ layer was removed, dried through anhydrous sodium sulfate and transferred to GC vials. The prepared FAME derivatives were analyzed by GC-MS (details given above), using the temperature profile of 40 °C (1 min) to 320 °C at 5 °C/min. The eluted compounds were identified with authentic standards (C12 to C20 fatty acids) and by spectral matching with the NIST spectral library.

**Results and discussion**

**Extraction of plant material**

Soxhlet extraction of MS leaves with DCM and MeOH gave 2.71% and 4.48% yield respectively, a total of 7.49%. These results compare favorably with the yield obtained by soaking MS leaves in cold MeOH (6%). Our previous observation$^7$ from study of another plant material (Cola nitida) subjected to similar treatment was different: soxhlet extraction gave a total of 18.37% yield, while soaking in cold MeOH gave 4%. Collectively, therefore, these data suggest that different plant materials may require different extraction techniques.

**Phytochemical screening**

The qualitative phytochemical screening of MS leaves showed the presence of alkaloids, tannins, cardiac glycoside, saponins and steroid, while no flavonoid was detected; although, an earlier report indicated the presence of flavonoid in aqueous extract of MS.$^{10}$ Tannins, flavonoids, saponins, cardiac glycosides and alkaloids have been reported to exhibit antimicrobial activities.$^{11,12}$

Alkaloids have antiarrheal, antihypertensive, antiinflammmatory, antiinfective and antifibrogenic effects.$^{13}$ Some alkaloids are useful against human immunodeficiency virus infection as well as intestinal infection associated with acquired immunodeficiency syndrome.$^{14}$ The presence of alkaloids in medicinal plants makes it recommendable for their treatment of one ailment or another, as alkaloids possess significant pharmacological properties.

Tannin is a nontoxic substance and can generate physiological responses in animals that consume it.$^{15}$ However, tannin can be toxic to filamentous fungi, yeast, and bacteria. The presence of tannin in medicinal plants suggests the ability of the plant to play major roles as an antifungal, antiarrheal, antioxidiant and antimhemorrhoidal agent.$^{16}$ The antibacterial properties of tannins have been documented.$^{17}$

Saponins have been reported to have antihyper-cholesterol, antiinflammmatory, cardiac depressant properties and appear to kill or inhibit cancer cells without killing normal cells in the process.$^{18,19}$

Steroids are biologically active organic compounds with four rings. They constitute important components of cell membranes which alter membrane fluidity and act as signaling molecules.$^{20}$ Steroids play critical roles in a number of disorders, including malignancies like prostate cancer and as antiinflammmatory agents.$^{11}$

Cardiac glycoside has been used for over two centuries as a
stimulant in cases of cardiac failure and diseases.\textsuperscript{22,23} This, perhaps, justifies the local use of MS in the treatment and management of hypertension.\textsuperscript{24}

**Antibacterial activity**

*In-vitro* activity of the extract and fractions against selected bacteria

The *zone of inhibition* (the diameter of the circular region around the well, where there was no microbial growth) due to EtOAc fraction was 15 mm for both *B. subtilis* and *B. cereus*; there was no inhibition of growth for *E. coli*, *P. aeruginosa*, and *S. aureus*. The crude MeOH extract exhibited a zone of inhibition of 13 mm and 12 mm against *B. subtilis* and *B. cereus* respectively and no inhibition of growth on *E. coli*, *P. aeruginosa*, and *S. aureus*. The n-hexane fraction displayed zones of inhibition of 12 mm and 11 mm for *B. subtilis* and *B. cereus* but also no inhibition of growth on *E. coli*, *P. aeruginosa*, and *S. aureus*. The n-butanol fraction showed no inhibition of growth for any of the bacterial strains tested. The result is shown in Table 1. This result showed that bioactivity of the MS leaf is centered in the EtOAc fraction; hence, it was considered for further chemical examination. To note, among the tested microbes, only *Bacillus* species were responsive to the activity of MS crude MeOH extract and fractions. The activity of the EtOAc fraction against *Bacillus* species was comparable to that of ciprofloxacin.

**MIC and MBC of the EtOAc fraction**

The MIC of the EtOAc fraction against the *Bacillus* species was investigated, as well as its MBC. MIC of 0.313 mg/mL was observed on *B. subtilis* and *B. cereus*, while the MBC value of >40 mg/mL was obtained for the EtOAc fraction. However, the high MIC value implies higher dose for effective treatment compared to ciprofloxacin. When MS MeOH extract was administered to experimental animals (mice), the LD\textsubscript{50} of 1625 was observed, implying a high safe dose for treating animals with MS extract against microbial attack.

**Chemical constituents analysis**

*GC-MS analysis of n-hexane fraction*

The n-hexane fraction was analyzed by GC-MS and compounds identified based on NIST 08 MS library matching (Table 2). The

14 components identified included phytol (26%), methyl-9,12,15-octadecatrienoate (20.9%), and methyl-9,12-octadecadienoate (11.1%) as the main components. Phytol is an acyclic diterpene alcohol.

An analysis of MS leaf DCM and CH$_2$OH extracts

ESI-MS analysis

Five compounds were tentatively identified in the positive ion ESI-MS analysis of the DCM extract; the mass spectrum is shown in Supplementary Figure S1. 3-O-$\beta$-D-glucuronopyranosyl-oleanolate (GrGOa) gave low intensity ions at m/z 795, 799, 903 corresponding to [M + H]$^+$ (12%), [M + 5H]$^+$ (20%), [M + H + 6H$_2$O]$^+$ (25%) and a high intensity ion at m/z 1029 corresponding to [M + H + 13H$_2$O]$^+$ (70%). 3β-O-[α rhamnopyranosyl-(1→6)-β-glucopyranosyl-(1→3)-ursan-12-ene (RGUe) gave rise to high intensity ions with m/z 1015, 871 corresponding to [M + H + 17H$_2$O]$^+$ (70%), [M + H + 9H$_2$O]$^+$ (100%) and a less intensity ion at m/z 925 corresponding to [M + H + 9H$_2$O]$^+$ (48%). 3-O-[[β-D-glucopyranosyl (1→2)] [β-D-glucuronopyranosyl]-oleanolic acid (GXGrOA) gave low intensity ion at m/z 969 corresponding to [M + acetyl]$^+$ (22%). 3-O-[[β-D-glucopyranosyl (1→2)] [β-D-glucuronopyranosyl]-oleanolate (GXGrGOa) gave rise to low intensity ions with m/z 1111 and 1127 corresponding to [M + Na]$^+$ (18%) and [M + K]$^+$ (25%) respectively. 3β-acetoxyolean-12-ene (AoOe) gave rise to moderately intense ion at m/z 955 corresponding to [M + H + 27H$_2$O]$^+$ (58%).

The following five compounds were also identified in the methanol extract (Supplementary Fig. S2): GrGOa at m/z 903 and 1029 corresponding to [M + H + 6H$_2$O]$^+$ (16%) and [M + H + 13H$_2$O]$^+$ (24%) respectively; RGUe at m/z 925 corresponding to [M + H + 12H$_2$O]$^+$ (100%); AoOe at m/z 955 corresponding to [M + H + 27H$_2$O]$^+$ (55%); and GXGrGOa at m/z 927 corresponding to [M + H]$^+$ (25%) and GXGrGOa at with m/z 1111 corresponding to [M + Na]$^+$ (20%).

GC-MS analysis of DCM extract (FAME derivatives)

Five of the six compounds identified and quantified in the DCM extract (Supplementary Fig. S3, Table 3), after methanalysis, belong to oleanane and lupane triterpenoid series. The major component was olean-12-en-3-one, the oxidized product of olean-12-en-3-ol. The presence of olean-12-en-3yl acetate (3-β-acetoxyolean-12-ene) in the extract was supported by the ESI-MS result (Supplementary Fig. S1) and in agreement with the report of Penders and Delaude. 6

GC-MS analysis of DCM extract (TMS derivatives)

The DCM extract was also quantitatively analyzed by GC-MS for its TMS derivatives (Table 4). The analysis revealed the presence of eight different compounds, the major constituents being methyl-3-oxo-urs-12-en-24-oate and hop-22(29)-en-3-one.

IS, internal standard; MS, Melanthera scandens; MW, molecular weight; TMS: trimethylsilyl.
Chemical constituents of bioactive isolates

Analysis of fraction B1

n-Hexadecanoic acid was the main compound identified in the negative ion ESI-MS of B1, [M-H]: m/z 255 (100%). Minor components included methylhexadecanoate, methyl-9-octadecenoate, methyl octadecanoate and methyl eicosanoate m/z 269 (27%), 295 (11%), 297 (26%) and 325 (33%) respectively (Supplementary Fig. S4).

Fraction B1 was also analyzed by GC-MS for its TMS derivatives. TMS hexadecanoate was the main constituent (7.2% of extract), followed by TMS octadecanoate (0.55% of extract). Thus, n-hexadecanoic acid was the main constituent of B1; this was ascertained by the ESI-MS, FAME and TMS GC-MS analyses results.

NMR spectroscopy of B1

1H-NMR (400 MHz, CDCl3, δ ppm) showed the presence of methylene protons at upfield region δ values 2.35, 1.64, 1.28 and methyl protons at δ 0.90 ppm. No olefinic or aromatic proton was observed. Additional findings were 13C-NMR (100 MHz, CDCl3, δ ppm) 180.39 (C=O carbon typical of carboxylic acids) 34.29–22.87 (methylene carbon atoms), and 14.26 methyl carbon. The NMR data above are in agreement with literature values for hexadecanoic acid.

Analysis of fraction D1

Isolated fraction D1 was analyzed by positive ion ESI-MS, and the major peak at m/z 917 (100%) was unidentified (Supplementary Fig. S5). Tentatively identified components in D1 included eupalestin as [M + H + nH2O]+, n = 9 at m/z 579; 3-β-D-glucuronopyranosyl-oleanolic acid as [M + nH]+, n = 7 at m/z 639; and 3-β-D-glucuronopyranosyl (4→1) β-D-xylpyranosyloxymethylene oleic acid as [M + K]+ at m/z 803.

Fraction D1 was methanolized and analyzed by GC-MS, showing the presence of methyl hexadecanoate.

Fraction D1 was also analyzed by GC-MS for its TMS derivatives, showing the presence of 9-decenoate-TMS together with minor amounts of 1-heneicosanol-TMS plus three other compounds (Table 5).

Analysis of fraction G1

Fraction G1 was analyzed by GC-MS as its TMS derivatives, showing the presence of 9-decenoate-TMS together with minor amounts of 1-heneicosanol-TMS (0.11% of extract).

Analysis of fraction I

Isolated fraction I was identified by positive ion ESI-MS and the major peak at m/z 917 (100%) was 9,10-dimethyltricyclo[4.2.1.1(2,5)]decane-9,10-diol (2.58% of extract) together with methyl hexadecanoate (1.02% of extract).

Fraction I was also analyzed by GC-MS for its TMS derivatives, showing the presence of indole-5-carboxylic acid-TMS2 (0.08% of extract), 4-hydroxybenzoic acid-TMS2 (0.08% of extract), and p-aminosalicylic acid-TMS (0.08% of extract).

Analysis of fraction K1

Positive ion ESI-MS analysis of fraction K1 showed the presence of three compounds (Supplementary Fig. S6). 3-O-[β-D-xylpyranosyl (1→4) β-D-glucuronopyranosyl]-oleanolic acid was identified as moderately intense ion at m/z 803 corresponding to [M + K]+ (52%). Methyl hexadecanoate gave low intensity ion at m/z 288 (36% of extract), which resulted from the gain of water molecule [M + H2O]+. Dihydro-lycopsamine ion showed at m/z 302 (29% of extract), as a result of protonation [M + H]+.

Fraction K1 was also methanolized and analyzed by GC-MS and showed the presence of typical FAME derivatives, mainly methyl-hexadecanoate. The results are given in Table 6.

MW, molecular weight; TMS: Trimethylsilyl.

Analysis of fraction K2

Positive ion ESI-MS tentatively identified four compounds.
Adesanwo JK. et al: Chemical constituents and antibacterial activity of M. scandens

(Supplementary Fig. S7) which are: those being lycopsamine N-oxide; oleanolic acid; 3-O-[β-D-xylopyranosyl (1→4) β-D-glucuronopyranosyl]-oleanolate and 3-O-[β-D-xylopyranosyl (1→4) β-D-glucuronopyranosyl]-28-O-β-D-glucopyranosyl-oleanolate, which were observed at m/z 316, 479, 806 and 949 corresponding to [M + H]$^+$ (62% of extract), [M + Na]$^+$ (34% of extract), [M + OAc]$^+$ (45% of extract) and [M + Na]$^+$ (35%) respectively.

The presence of dihydro-lycopsamine, lycopsamine N-oxide and eupalestin have been reported in the Ageratum conyzoides family Asteraceae.$^{25}$ 3β-acetoxyolean-12-ene and 3β-O-[α-rhamnopyranosyl-(1→6)-β-glucopyransyl-(1→3)-ursan-12-ene identified in the DCM and methanol extracts of MS have been reported in the Aspilia africana family Asteraceae.$^{26}$ Oleanolic acid, GrOA, GXGrOA, GXGrGOa, GrGOa, GXGrOOa and XGrGOa have been previously reported in MS.$^{6}$

Conclusions

This study concluded that the crude MeOH extract, which was found to contain alkaloids, tannins, cardiac glycosides, saponisins and steroids, inhibited the activities of Bacillus species considerably, among the microbes tested. The EtOAc solvent partitioned fraction was the most active, while the butanol fraction showed no activity. Many of the compounds identified in the MS extract in this work have been previously reported to have biological activity. Phytol, a diterpene alcohol and the major constituent of the n-hexane extract, is known to inhibit inflammatory response by reducing cytokine production and oxidative stress.$^{27}$ 1-Heptacosanol exhibited antimicrobial activity.$^{28}$ Oleanolic acid, a pentacyclic triterpenoid, and its derivatives exhibited several pharmacological activities, such as hepatoprotective, anti-inflammatory, antioxidant and antitumor, among others.$^{29,30}$ Long-chain fatty acids, such as hexadecanoic acid, octadecanoic acid, pentadecanoic acid, etc., have been reported several times over to possess various biological activities, including antimicrobial.$^{31,32}$ These chemical compounds are responsible for the bioactivities of the MS extract, including those of antibacterial, wound healing, anti-skin infections, antigastroenteritis, anti-inflammatory, antidiuretic, and antihypertensive, among others. These justify its use in ethno-medicine to manage diseases caused by pathogenic microorganisms.

Future research direction

The plant MS is used in both man and animals. We have reported our previous study of its toxicity in our earlier report, and the plant could be classified as nontoxic based on our findings. However,
there is still need for biochemical studies to determine its effect on internal organs in experimental animals.

Many of the chemical constituents of MS have been identified in the course of these detailed analyses. Since the ESI-MS analysis showed that there are some unidentified chemical components yet, future research should focus on identifying these.

A lot of screenings on antimicrobial activity of MS have been carried out by various authors, including those shown in our previous report, but there is need to screen the extract of this plant further against cancer cells and for its anti-inflammatory potentials among other biological activities.

Acknowledgments

We wish to acknowledge the University of Idaho, Moscow, USA, for the offer of a 6-month Research Scientist position, which afforded Armando G. McDonald the opportunity to carry out the analyses reported in this work.

Conflict of interest

The authors declare there is no conflict of interest related to this publication.

Author contributions

The owner of research idea and supervisor of the project (JKA), carrying out the experiments (ISA), assisting in supervision of the project when JKA travelled to USA for a six months research project in Armando’s laboratory (OSA), assisting in spectroscopic analysis (GMA).
